Archaeologists are fond of pointing out that "history" (in the general sense, meaning the study of the human past) does not begin with the advent of writing. People have always led dynamic, event-filled lives, as much so in nonliterate times as in those documented by texts. In the popular imagination, however, peoples and eras not recorded by scripts are frequently characterized as static, ahistorical, and homogeneous. As a result, archaeologists are continually at pains to emphasize the fact that past societies that did not make use of the written word were as varied and active as any other, and that history does not depend upon the existence of cuneiform tablets, hieroglyphs, or the invention of the alphabet. This is particularly true for archaeologists working in the precolonial contexts of what later became "settler societies" (the United States, Canada, Australia, New Zealand, and South Africa, among others), who are burdened with continually repeating the mantra that history does not begin with the arrival of Columbus, Pizarro, Captain Cook, John Smith, or (insert name of geographically appropriate European explorer here).

- ① a potential risk of relying on unrecorded major events
- ② efforts to dismiss misbelief about undocumented history
- ③ the problem of archaeologists relying on their intuition
- ④ the role of texts to enhance historical comprehension
- ⑤ the significance of writers in interpreting our ancestors' lives

In 1900, at the close of the first decade in which electric systems had become a practical alternative for manufacturers, less than 5 percent of the power used in factories came from electricity. But the technological advances of suppliers made electric systems and electric motors ever more affordable and reliable, and the suppliers' intensive marketing programs also (a) sped the adoption of the new technology. Further accelerating the shift was the rapid (b) expansion in the number of skilled electrical engineers, who provided the expertise needed to install and run the new systems. In short order, electric power had gone from exotic to commonplace. But one thing didn't change. Factories continued to build their own powersupply systems on their own premises. (c) Few manufacturers considered buying electricity from the small central stations. Designed to supply lighting to local homes and shops, the central stations had neither the size nor the skill to serve the needs of big factories. And the factory owners, having always supplied their own power, were (d) willing to assign such a critical function to an outsider. They knew that a glitch in power supply would bring their operations to a (e) halt — and that a lot of glitches might well mean bankruptcy. As the new century began, a survey found that there were already 50,000 private electric plants in operation, far surpassing the 3,600 central stations.

Playwright Caryl Churchill often workshops her plays using a communal method of development that allows actors to help create the script through improvisation and the director ① to co-determine the direction of the final script. Such was the case with Churchills play Cloud Nine, the story of several generations of a family and ② how they are governed by class, race, and gender – a play, by the way, that features cross-gender casting. Instead of writing in a private study room, she spent several weeks working with the director on the idea and setting for the play. Then actors ③ were brought in to improvise as they jointly workshoped the idea. Churchill took ④ what she learned and wrote a tentative script with rudimentary dialogue. This first script was again workshoped with the director and actors to refine the dialogue, and this collaboration ⑤ resulting in the final production.

Exfoliation weathering, also known as onion weathering, refers to peeling off concentric shells of rocks due to combined actions of heat and wind in hot arid and semi-arid regions and monsoon lands. Exfoliation is more common over crystalline rocks. The outer shells of rocks become loose due to ① alternate expansion and contraction due to high temperature during day time and comparatively low temperature during night respectively and these loosened shells are removed (peeled off) by strong winds. Differential heating of outer and lower shells of a rock mass ② causes flaking. The solar radiation goes through up to a few centimetres only in the rocks having ③ low thermal conductivity. Thus, the outer shells of such rocks expand more than the shells lying just below. This ④ uniform expansion of rock shells causes flaking wherein the thin rock sheets are detached from the rock mass. These detached rock sheets are later on removed by strong winds. Thus, sheets after sheets of rocks are peeled off and the rocks continue to be ⑤ bare.

The Amazon has long done its part to balance the global carbon budget, but new evidence suggests the climate scales are tipping in the world's largest rainforest. Now the Amazon is emitting more carbon than it captures due to the emissions from fires. ① In the Amazon, forests are often cut during the wet season, and burned during the dry season to make way for agribusiness. ② Decades of deforestation and fires in the Amazon coupled with the global climate crisis have caused the dry season to get longer and made mega droughts more common, contributing to a feedback loop that degrades forests. ③ These degraded conditions mean trees are dying at a faster rate and the Amazon's ability to absorb carbon from the atmosphere is declining. ④ The Amazon is not homogeneous; different regions have different types of soil, humidity, tree species, and differed capacity to absorb or emit carbon gases. ⑤ The world should find a way to reduce CO2 emission because we won't be able to rely on tropical forests to clean up after ourselves.

Companies increasingly rely on artificial intelligence to analyze consumer behavior and predict market trends. However, this practice raises serious ethical concerns. AI systems are often trained on data collected from limited populations, meaning that the resulting insights may not fairly represent minority groups or less active online users. As a result, marketing decisions based on such data can systematically favor certain consumers while ignoring others. In addition, the vast amount of personal information gathered, including browsing habits and purchase histories, creates significant privacy risks if mishandled. To address these problems, many researchers now recommend that companies disclose how their algorithms collect and use consumer data. Establishing independent review boards and requiring regular audits can help ensure that AI-based market research remains fair, transparent, and accountable to the public it studies.

AI-driven market research can ____ (A) ____ certain groups of consumers and expose their personal data, so companies should adopt clear ethical rules to make the process more ____ (B) ____ .
