1. 다음 글의 밑줄 친 부분 중, 어법상 틀린 것은? (3점)

Although the results from a probe mark the moment that observational cosmology came of age, the birth of the subject goes back to the astronomer Edwin Hubble. It is he who is credited with the discovery ① that the universe is expanding. Hubble studied light from many galaxies and found that the more distant ② ones were redder. It had been known that light waves from a receding source would be stretched and shifted toward the red end of the spectrum. Hubble found that the ③ bigger the red shift gets the farther away from us a galaxy is located and that the effect is the same in all directions. The simplest explanation of these facts, the one that Hubble announced to the world, ④ is that the galaxies are rushing away from us in an orderly pattern of expansion. Obviously, if the universe is expanding now, it must have been more compressed in the past. Using the measured rate of expansion, ⑤ which is easy enough to run the great cosmic movie backwards to determine that, many billions of years ago, all the galaxies would have been squeezed into one place.

Availability sort of works on the principle that if you can think of it, it must be important, ① which means it can also distort our thinking quite a lot. If you ask people for their views on what the most common crime is, for example, the majority will say murder. We almost always overestimate how ② frequently it occurs because murder is the crime we hear most about, through both the news media and TV dramas. It is actually quite rare in modern societies, but it gets a lot of publicity, so it is more cognitively available than other offenses – it comes most readily to mind. We have to think ③ much harder to identify other types of criminal activity – unless they are part of our recent experience, of course. Asking someone whos been recently burgled about what they think the most common crime is ④ to get quite a different result! Availability heuristics sometimes work in our favor. It can, for instance, help us to deal with a tricky problem if we can bring to mind ⑤ how someone else dealt with a similar one.

Anchoring bias describes the cognitive error you make when you tend to give more weight to information arriving early in a situation ① compared to information arriving later – regardless of the relative quality or relevance of that initial information. Whatever data is presented to you first when you start to look at a situation can form an "anchor" and it becomes significantly more challenging ② to alter your mental course away from this anchor than it logically should be. A classic example of anchoring bias in emergency medicine is "triage bias," ③ where whatever the first impression you develop, or are given, about a patient tends to influence all subsequent providers seeing that patient. For example, imagine two patients presenting for emergency care with aching jaw pain that occasionally ④ extends down to their chest. Differences in how the intake providers label the chart — "jaw pain" vs. "chest pain," for example — ⑤ creating anchors that might result in significant differences in how the patients are treated.

*triage: 부상자 분류 **intake provider: 환자를 예진하는 의료 종사자
