When talking in general about Roman women, things break down by time periods and by classes. Whether a woman was a slave or ① came from a wealthier class made a great deal of difference. It also made a difference ② which period you're talking about. Rome's conquests meant ③ that men were often away for long periods of time and might not come back at all. Women were ④ left in charge of making sure that things got done. After the conquests, the enormous wealth ⑤ bringing back to Italy allowed middle- and upper-class women to run things with more independence and power.

Consider The Wizard of Oz as a psychological study of motivation. Dorothy and her three friends work hard to get to the Emerald City, overcoming barriers, persisting against all adversaries. They do so because they expect the Wizard to give ① them what they are missing. Instead, the wonderful (and wise) Wizard makes them aware that they, not he, always had the power ② to fulfill their wishes. For Dorothy, home is not a place but a feeling of security, of comfort with people she loves; it is wherever her heart is. The courage the Lion wants, the intelligence the Scarecrow longs for, and the emotions the Tin Man dreams of ③ being attributes they already possess. They need to think about these attributes not as internal conditions but as positive ways ④ in which they are already relating to others. After all, didn't they demonstrate those qualities on the journey to Oz, a journey ⑤ motivated by little more than an expectation, an idea about the future likelihood of getting something they wanted?

Observations are not always undertaken with a clear sense of what data may be relevant. Think, for example, of a detective at the scene of a crime. What small details need to be noted or perhaps ① preserved for future reference? Moreover, a set of observations may yield unanticipated information – data that does not conform to the observers sense of what is relevant – but information that is nonetheless of some importance. Recently, medical researchers at a large university ② were studying the effect of calcium on pregnancy-related high blood pressure. Though they observed no significant reductions in the blood pressure of the women in their study who took calcium, they did notice something quite interesting and ③ unexpecting. The women in their study who took calcium during pregnancy had lower rates of depression than those who took a placebo instead of calcium. As a result, the researchers began an entirely new study, one designed to determine the extent to ④ which calcium can prevent depression in pregnant women. As this example suggests, it is important not to become too attached to ⑤ fixed notions of what may constitute relevant observational data. Otherwise, we run the risk of missing something that may turn out to be significant.
