Dear Mr. Kayne, I am a resident of Cansinghill Apartments, located right next to the newly opened Vuenna Dog Park. As I live with three dogs, I am very happy to let my dogs run around and safely play with other dogs from the neighborhood. However, the noise of barking and yelling from the park at night is so loud and disturbing that I cannot relax in my apartment. Many of my apartment neighbors also seriously complain about this noise. I want immediate action to solve this urgent problem. Since you are the manager of Vuenna Dog Park, I ask you to take measures to prevent the noise at night. I hope to hear from you soon. Sincerely, Monty Kim

Scientists use paradigms rather than believing them. The use of a paradigm in research typically addresses related problems by employing shared concepts, symbolic expressions, experimental and mathematical tools and procedures, and even some of the same theoretical statements. Scientists need only understand how to use these various elements in ways that others would accept. These elements of shared practice thus need not presuppose any comparable unity in scientists' beliefs about what they are doing when they use them. Indeed, one role of a paradigm is to enable scientists to work successfully without having to provide a detailed account of what they are doing or what they believe about it. Thomas Kuhn noted that scientists "can agree in their identification of a paradigm without agreeing on, or even attempting to produce, a full interpretation or rationalization of it. Lack of a standard interpretation or of an agreed reduction to rules will not prevent a paradigm from guiding research."

A defining element of catastrophes is the magnitude of their harmful consequences. To help societies prevent or reduce damage from catastrophes, a huge amount of effort and technological sophistication are often employed to assess and communicate the size and scope of potential or actual losses. This effort assumes that people can understand the resulting numbers and act on them appropriately. However, recent behavioral research casts doubt on this fundamental assumption. Many people do not understand large numbers. Indeed, large numbers have been found to lack meaning and to be underestimated in decisions unless they convey affect (feeling). This creates a paradox that rational models of decision making fail to represent. On the one hand, we respond strongly to aid a single individual in need. On the other hand, we often fail to prevent mass tragedies or take appropriate measures to reduce potential losses from natural disasters.

Regulations covering scientific experiments on human subjects are strict. Subjects must give their informed, written consent, and experimenters must submit their proposed experiments to thorough examination by overseeing bodies. Scientists who experiment on themselves can, functionally if not legally, avoid the restrictions ① associated with experimenting on other people. They can also sidestep most of the ethical issues involved; nobody, presumably, is more aware of an experiment's potential hazards than the scientist who ② devised it. Nonetheless, experimenting on oneself remains deeply problematic. One obvious drawback is the danger involved; knowing that it exists ③ is done nothing to reduce it. A less obvious drawback is the limited range of data that the experiment can generate. Human anatomy and physiology vary, in small but significant ways, according to gender, age, lifestyle, and other factors. Experimental results derived from a single subject ④ are, therefore, of limited value; there is no way to know if the subject's responses are typical or atypical of the response of humans as a group.

People often assume that synthetic food ingredients are more harmful than natural ones, but this is not always the case. Typically, synthetic ingredients can be made in a precisely controlled fashion and have well-defined compositions and properties, allowing careful evaluation of their potential toxicity. On the other hand, natural ingredients often vary appreciably in their composition and properties depending on their origin, the time of year they were harvested, the climate they experienced throughout their lifetime, the soil quality, and how they were isolated and stored. These variations can make testing their safety extremely difficult — one is never sure about the potential toxicity of minor components that may vary from time to time. In some cases, a natural food component has been consumed for hundreds or thousands of years without causing any obvious health problems and can, therefore, be assumed to be safe. However, one must still be very careful.

The ____ (A) ____ of the production process for synthetic food ingredients and the variability of natural food ingredients may ____ (B) ____ people's commonly held assumption that the natural ingredients are more secure.
